

# # Decision Tree assignment:

Outlook (y(9)/N(5))

Sunny (y(2)/N(3))

overcast (y(4)/N(6))

Rain (y(3)/N(2))

gain

Using the function for gain & entropy provided in the Jupyter notebook, and doing calculations,

$$\text{gain} = (\text{entropy}(9,5), [5/14, 4/14, 5/14], [\text{entropy}(2/3), \text{entropy}(3/2)])$$

$$= 0.24$$

Temp. (y(5)/N(5))

Hot (y(2)/N(2))

mild (y(4)/N(2))

cool (y(3)/N(1))

$$\text{gain} = (\text{entropy}(9,5), [4/14, 6/14, 4/14], [\text{entropy}(2,2), \text{entropy}(4,2), \text{entropy}(3,1)])$$

$$= 0.03$$

Humidity (9/5)

High (y(3)/N(4))

Normal (y(6)/N(1))

$$\text{gain} = (\text{entropy}(9,5), [7/14, 7/14], [e(3,4), e(6,1)])$$

$$= 0.15$$

Wind (y(9)/N(5))

Weak (y(6)/N(2))

Strong (y(3)/N(3))

$$\text{gain} = (\text{entropy}(9,5), [8/14, 6/14], [\text{entropy}(6,2), e(3,3)])$$

$$= 0.04$$

Now, the 'outlook' is the root node, as there ~~are~~ is max gain in it.

For the root node, Sunny,

Temp. (y(2)/N(3))

Hot (0/2)

Mild (1/1)

cool (1/0)

$$\text{gain} = (\text{entropy}(2,3), [2/5, 2/5, 1/5], [0, e(1,1), 0])$$

$$= -0.02$$

Humidity (2/3)

High (0/3)

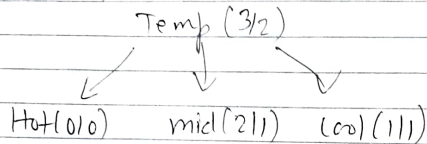

Normal (2/0)

$$\text{gain} = (\text{entropy}(2,3), [3/5, 2/5], [0, 0])$$

$$= 0.97$$

Since, the gain is max in humidity, the second root node becomes "Sunny".

Now, for Rain,

$$\text{Gain} = (\text{entropy}(3,2), [3/5, 2/5], [\text{entropy}(2,1), \text{entropy}(1,1)])$$

$$= 0.01$$

$$\text{Gain} = (\text{entropy}(3,2), [2/5, 3/5], [\text{entropy}(1,1), \text{entropy}(2,1)])$$

$$= 0.01$$

$$\text{Gain} = (\text{entropy}(3,2), [3/5, 2/5], [0, 0])$$

$$= 0.97$$

Therefore, the wind is the root node for this case as it has the maximum value.

Hence, the final decision tree is presented below:
